

What flux value to choose for royal blue?

www.lec-expert.com

[Read this article on the website \(URL\)](#)

Royal blue is a very deep blue. Usually, LEC gives values in watts rather than lumens, because in this lightwave range:

- human eye perception is decreases considerably acco,
- the value expressed in lumen is low,
- daytime and night-time vision are not the same.

Note: As photopic (daytime) and scotopic (night-time) vision are different, lumen values vary depending on the ambient light.

For example, here are two LED wavelengths for a flow of 489 mW.

Daytime luminous flow

- at 455 nm = 16.3 lm
- at 460 nm = 20 lm

Night-time luminous flow

- at 455 nm = 425 lm
- at 460 nm = 471 lm

Two measures of light energy

Watts and lumens are two ways of describing the same thing, only using different units.

- **Watt (W)** characterizes the universal and absolute size of electrical power. This value corresponds to the **energy flow**.
- **Lumen (lm)** is the size used in the world of lighting technology. This value takes into account eye response, and corresponds to the **visual flow**.

Thus, a watt in green and a watt in blue do not give the same response in terms of lumens. There are many more lumens in green, than in blue where the eye is not very sensitive.
